

Updated research plan:

- Compile a list of roadside and highway IoT device categories and vendors that can scan, detect, or passively collect Wi-Fi or Bluetooth signals.
 - Gather official product specifications and datasheets from primary vendor sources, prioritizing technical documentation over secondary summaries.
 - Build a comparative matrix covering model, vendor, form factor, power source, mounting, supported sensors, frequency bands, detection modes, MAC anonymization handling, on-device processing, storage, backhaul, APIs/protocols, price range, certifications, and any fields marked as unspecified where data is unavailable.
 - Collect representative deployment case studies from transportation agencies, smart city programs, tolling operators, and vendor references.
 - Survey academic and industry papers on roadside Wi-Fi/Bluetooth sensing, focusing on methods, limitations, and reported accuracy metrics.
 - Synthesize the findings into an analytical report with an executive summary, comparison tables, official datasheet links, and a timeline or system-flow diagram showing how roadside signal collection systems typically operate.
-
